Institute for Safe Medication Practices Canada
Overview

1. Introduction to ISMP Canada
2. Examples of Ontario Leadership
3. Value of Reporting
Advancing safe medication use

The Institute for Safe Medication Practices Canada is an independent national not-for-profit organization committed to the advancement of medication safety in all healthcare settings. ISMP Canada works collaboratively with the healthcare community, regulatory agencies and policy makers, provincial, national and international patient safety organizations, the pharmaceutical industry and the public to promote safe medication practices. ISMP Canada's mandate includes analyzing medication incidents, making recommendations for the prevention of harmful medication incidents, and facilitating quality improvement initiatives.

Reporting and Prevention Systems

Medication Incident and Near Miss Reporting Programs for:
- Practitioners
- General Public

Medication Incident Analysis

1. Shared learning from medication incidents helps identify system improvement opportunities
2. Solution development involves consultation and collaboration
Wrong injection causes death

BY GRAEME SMITH

A drug used to execute death-row prisoners was mistakenly injected into an elderly woman, whose death in a Peterborough, Ont., hospital will be examined in a coroner’s inquest.

Bonita Porter, Ontario’s deputy chief coroner of inquests, announced yesterday that a jury will look at why Frances Marie Tanner, 84, died at the Peterborough Regional Health Centre on Jan. 21.

The cause of Ms. Tanner’s death is already known: Somebody injected a dose of potassium chloride into her vein. Small quantities of the drug can cure potassium deficiencies, but larger amounts are poisonous.

At least three other Canadians have died after receiving the same drug, sometimes from nurses who thought it was a different medicine.

Some doctors blame these accidents on manufacturers who sell potassium chloride in plastic ampoules and vials that closely resemble containers of sterile water, saline solution, and other harmless solutions.

Others say hospitals need stricter controls over potentially deadly substances. Ontario’s chief coroner sent a memo to hospitals last year specifically warning them that potassium chloride has been wrongly administered in the past.

After the latest death, however, the coroner’s office decided it was time to emphasize the danger.

“It was felt that an inquest might be the best way to get the information out,” Dr. Porter said.

The medical community knows surprisingly little about its own errors. A newsletter published last month by the Institute for Safe Medication Practices Canada recorded five cases in which patients were accidentally given potassium chloride; three died, and two were considered “near misses.”

More cases could exist, said the institute’s president, physician David U. While many hospitals have removed potassium chloride from nursing stations, he said, some doctors still demand to have it on hand, particularly in intensive-care units. And the drug manufacturers have a financial interest in maintaining their products’ unform packaging.

“If the companies have just one assembly line, so they all look the same,” he said. “It’s an accident waiting to happen.”

Researchers have suggested that perhaps 5,000 to 10,000 Canadians die because of medical error in hospitals every year.

The estimate is extrapolated from just one American study, however. A Canadian study was launched last month.
Initiative to eliminate concentrated potassium chloride from patient care areas was supported by MOHLTC.

Similar packaging and storage contributed to fatal errors.
Provincial Advisory Committee

- Ontario Ministry of Health and Long-Term Care
- Ontario Hospital Association
- Registered Nurses Association of Ontario
- Registered Practical Nurses of Ontario
- Ontario Medical Association
- Ontario Pharmacists’ Association

Province-wide effort
ISMP Canada Activities for the CMIRPS:

- Reporting Systems for Medication Incidents
- A consumer medication safety reporting and learning program: SafeMedicationUse.ca
- Safety bulletins and alerts by ISMP Canada about medication incidents and prevention strategies
- Medication Safety Self-Assessment programs
- Root Cause Analysis workshops and frameworks
- Failure Mode and Effects Analysis workshops and frameworks
- Responding to queries on medication safety (email or telephone)
- Medication safety workshops and webinars

CMIRPS Web site

ISMP Canada is pleased to announce that CMIRPS Web site has been officially launched.

This new Web site is now available with information on the Canadian Medication Incident Reporting and Prevention System (CMIRPS), a collaborative program to reduce and prevent harmful medication incidents in Canada.

Health Canada, the Canadian Institute for Health Information (CIHI), the Institute for Safe Medication Practices Canada (ISMP Canada) and the Canadian Patient Safety Institute (CPSI) are partnering to contribute information, tools and expertise in the prevention of harmful medication incidents.

Visit the new CMIRPS Web site today for more information about the program and its partners.

Reports involving Neuromuscular Blocking Agents
Neuromuscular Blocking Agent Labelling and Packaging Initiative

A collaborative meeting of representatives of pharmaceutical manufacturers of neuromuscular blocking agents was convened by ISMP Canada in Toronto on February 27th, 2006. The foremost outcome was agreement among the attending stakeholders on the “ideal features” for packaging and labeling of neuromuscular blocking agents:

1. Red cap with white lettering: “Paralyzing agent” or “Warning: Paralyzing Agent”
2. Red ferrule with white lettering: “Paralyzing agent”
3. Red lettering on the product label: “Paralyzing agent” or “Warning: Paralyzing Agent”
4. Peel-off label, using the colour scheme and content information recognized by the ASA/CAS recommended standards, for application to a prepared syringe (ASA = American Society of Anesthesiologists (www.asahq.org); CAS = Canadian Anesthesiologists’ Society (www.cas.ca))
5. Space on the product label for bar code application
6. Development of a universal symbol for neuromuscular blocking agents and proposal for global use: placement of this symbol (e.g., on the label), to be determined
7. Review of potential benefit of using TALL-man lettering for generic names of neuromuscular blocking agents

Participating manufacturers (Sandoz Inc, Hospira, Organon, and Abbott) are evaluating the feasibility of incorporating some or all of these features.
Result: Package and Label Changes
Moving Forward

Knowledge Transfer

Work has informed Health Canada’s Draft Guidance Document - Labelling of Pharmaceutical Drugs for Human Use

- Designed to facilitate compliance with regulated labelling requirements.
- Supports safe and effective use of drugs

Drug Interaction Incident with HIV Post-exposure Prophylaxis

The regimens for post-exposure prophylaxis (PEP) against human immunodeficiency virus (HIV) consist of combinations of antiretroviral medications. These medications are taken for a period of 4 weeks to reduce the risk of HIV infection in people who may have been exposed to the virus, either through occupational exposure (e.g., needlestick injuries) or non-occupational exposures (e.g., sexual assault).\(^1\,^2\,^3\) They must be started as soon as possible (preferably within hours of exposure);\(^1\,^2\,^3\) therefore, if the person is deemed a suitable candidate for prophylaxis, an HIV PEP “starter kit” is often provided in the emergency department or other ambulatory setting to ensure prompt initiation. The process for supplying the balance of the HIV PEP medication varies. The medications may be dispensed by a community pharmacy or may be provided during follow-up clinic visits. When providing HIV PEP, a systematic approach for identifying possible drug interactions may be lacking.

Certain antiretroviral medications are known to be involved in numerous drug interactions through their inhibition of the

- The clinically significant drug interaction between ritonavir and fentanyl was not identified.

Ritonavir is a potent inhibitor of the CYP 3A4 enzyme which is responsible for metabolizing fentanyl.\(^6\) A study evaluating the interaction between ritonavir and intravenous fentanyl found that fentanyl clearance was reduced to one third when ritonavir 200 mg, given three times per day, was added. The authors conclude that ritonavir treatment results in an approximately three-fold increase in fentanyl concentrations,\(^7\) an interaction of major clinical significance.\(^8\) Administration of Kaletra for HIV PEP delivers a ritonavir dose of 100 mg twice per day. Studies of the increase in fentanyl concentration occurring as a result of an interaction with a lower dose of ritonavir (as in the HIV PEP protocol) have not been published. Of interest, the product monographs for the fentanyl patch (e.g., Duragesic)\(^9\) do list ritonavir as an interacting drug. However, the ritonavir product monographs (Kaletra,\(^10\) Norvir,\(^11\) and Norvir SEC\(^11\) ), do not include fentanyl in the

Heparin-Induced Thrombocytopenia — Effective Communication Can Prevent a Tragedy

An otherwise healthy 63-year-old patient was admitted to hospital for elective mitral valve replacement surgery. Unfractionated heparin (UFH) was administered according to protocol during the surgical procedure, and full-dose UFH was administered intravenously for several days afterward, until a therapeutic international normalized ratio (INR) was attained with oral warfarin. The platelet count was 96 x 10^9/L (normal range 150-400 x 10^9/L) immediately after surgery and rose to 142 x 10^9/L by the fifth postoperative day. Over the next two days the platelet count fell to 54 x 10^9/L. Because of the decline in the platelet count, the physician ordered an assay to detect for the presence of the antibody responsible for heparin-induced thrombocytopenia (HIT). On the following day, the positive results of the HIT antibody assay were posted in the laboratory section of the electronic patient record (EPR). As well, a paper copy of the laboratory report was sent to the ward; however, the patient had been discharged earlier that day, and the report was placed with other materials to be sent to the health records department for filing.

Approximately one week later, the patient presented to the emergency department of the same hospital complaining of shortness of breath. The differential diagnosis included pleural effusion and pulmonary embolus.

... problems can ensue when there is no coordinated system to ensure communication and documentation of critical test results and drug allergy information.

The devastating case of HIT described above illustrates some of the problems that can ensue when there is no coordinated system to ensure communication and documentation of critical test results and drug allergy information. Although this patient received appropriate platelet count monitoring and detection of HIT antibodies during the original hospital admission, the failure to adequately communicate and document this information led to inappropriate re-administration of UFH, with a catastrophic
Designing a National Strategy for Healthcare

In an effort to increase patient safety, members of the healthcare industry are collaborating to implement standardized bar codes on all aspects of pharmaceutical labelling.

Headed jointly by the Institute for Safe Medication Practices Canada (ISMP Canada) and the Canadian Patient Safety Institute (CPSI), the initiative is guided by a national Implementation Committee and being developed with assistance from a 34-member Technical Task Force (TTF), representing six identified healthcare sectors.

ISMP Canada and CPSI jointly endorsed the adoption of the GS1 global standard for automated identification (e.g., bar coding) of pharmaceutical products in Canada.

The multiphase project has developed draft technical requirements for bar codes on drug labels, and is working with the Canadian and American health sectors to implement them.
Pharmaceutical Bar Coding Project

Major Objectives:

- To develop a pan-Canadian strategy for bar coding of commercial pharmaceutical products.
- To select a common product database for standardized product data.
- To facilitate clinical information systems development which utilizes automated identification and data capture at each point of the medication chain.
- To create a national environment for automated identification implementation within each identified healthcare sector.
"Efforts to make patient care safer will require leadership to encourage the reporting of AEs, continued monitoring of the incidence of these events, the judicious application of new technologies and improved communication and coordination among caregivers."

## Distinction between Adverse Drug Reactions and Medication Incidents

<table>
<thead>
<tr>
<th>Adverse Drug Reaction Reporting</th>
<th>Medication Incident Reporting</th>

Fentanyl transdermal patch and fatal adverse reactions

The fentanyl transdermal system is indicated for the management of moderate to severe chronic pain that cannot be managed by other means such as opioid combination products or immediate-release opioids. The safety of this system is contingent on its use according to the conditions recommended in the Canadian product monograph. The fentanyl transdermal system has been marketed in Canada under the brandname Duragesic since 1992. In July 2006, 2 generic products were introduced: Ratio-Fentanyl and Ran-Fentanyl transdermal systems. Health Canada continues to monitor reports of serious adverse reactions (SARS) suspected of being associated with fentanyl transdermal patches. Fatal outcomes were previously described in this newsletter involving opioid-naive adolescents and adolescents who abused this medication. The Canadian product monograph for Duragesic was revised in 2005 to emphasize safety information following reports of death related to inappropriate use of this product. Related advisories were issued in September 2005. Numerous publications have highlighted safety issues related to the use of fentanyl patches.

From Jan. 1, 1992, to Dec. 31, 2007, Health Canada received 105 reports of AIs suspected of being associated with fentanyl transdermal patches wherein a fatal outcome was reported. Twenty-seven of the reports were received after the last Health Canada risk communications. As part of the ongoing monitoring of AR reports, the data were analyzed to identify potentially preventable incidents and to increase awareness regarding the safe use of this product. In 33 of the 105 reports, the cause of death was reported to be unrelated to the fentanyl transdermal patches; in 20 cases, insufficient information was provided in the report for evaluation. The remaining 52 reports are summarized in Table 1.

Health care professionals are reminded to follow the directions in the product monographs for fentanyl transdermal patches. Guidance on the safe use of this product is essential for patients, caregivers, and their families, including the safe storage of fentanyl patches to prevent their accessibility for abuse and prevention of accidental overdose.

Acknowledgement: Health Canada acknowledges the collaboration with Sylvia Hyland, RPh, BScPharm, MSc(Geopharm), of the Institute for Safe Medication Practice Canada (ISMP Canada) and member of the Expert Advisory Committee on the Vigilance of Health Products, in the analysis of this data and preparation of this article.
Core Principles of Reporting

• Reporting must be safe - individuals who report incidents must not be punished or suffer other ill-effects from reporting. Reporting is only of value if it leads to a constructive response.

• The most important function of a reporting system is to use the results of data analysis and investigation to formulate and disseminate recommendations for system improvements.

• A reporting system must produce a visible, useful response to stimulate improvement and continued reporting.
Why is Reporting Important?

• Learning from experience can prevent harmful mistakes from recurring. Safety is enhanced by learning from failures.

• Meaningful analysis, learning, and system improvement requires collaboration at all levels.
